

FEATURES

- Filterless mono, digital input Class-D amplifier**
- I²C control interface**
- Serial digital audio interface supports common formats (I²S, PCM, LJ, RJ, TDM1-16, PDM)**
- Supports wide range of sample rates: 8.0 kHz to 96.0 kHz**
- MCLK and BCLK can be provided by built-in phase-locked loop (PLL)**
- Supports single power supply mode; DVDD can be provided by built-in low dropout (LDO) regulator**
- 2.5 V to 5.5 V SPKVDD operating supply voltage**
- 1.08 V to 1.98 V DVDD operating supply voltage**
- Support off-chip volume control without I²C**
- 2.4 W into 4 Ω and 1.4 W into 8 Ω at 5 V supply with <1% THD + N**
- Available in a 16-ball, 1.92 mm \times 1.94 mm, 0.4 mm pitch WLCSP**
- Efficiency 95% at full scale into 8 Ω**
- Signal-to-noise ratio (SNR): 103 dB, A-weighted**
- Power supply rejection ratio (PSRR): >80 dB at 217 Hz**
- Digital volume control: -70 dB to +24 dB in 0.375 dB steps**
- Ultralow idle current**
- Autosample rate detection**
- Pop-and-click suppression**
- Short-circuit and thermal protection with programmable autorecovery**
- Supports smart power-down when no input signal is detected**
- Power-on reset and UVLO voltage monitoring**
- Selectable ultralow EMI emission mode**
- Supports SPKVDD voltage monitor**
- Digital audio processing**
 - 7-band programmable equalizer**
 - Programmable dynamic range compression (DRC) with noise gate, expander, compressor, and limiter**

APPLICATIONS

- Mobile phones**
- Portable media players**
- Laptop PCs**
- Wireless speakers**
- Portable gaming**
- Navigation systems**

GENERAL DESCRIPTION

The **SSM2529** is a digital input, Class-D power amplifier that combines a digital-to-analog converter (DAC), a low power audio specific digital signal processor, and a sigma-delta (Σ - Δ) Class-D modulator.

This unique architecture enables extremely low real-world power consumption from digital audio sources with excellent audio performance. The **SSM2529** is ideal for power sensitive applications, such as mobile phones and portable media players, where system noise can corrupt small analog signals that are sent to an analog input audio amplifier.

Using the **SSM2529**, audio data can be transmitted to the amplifier over a standard digital audio serial interface, thereby significantly reducing the effect of noise sources such as GSM interference or other digital signals on the transmitted audio. The closed-loop digital input design retains the benefits of an all-digital amplifier, yet enables very good PSRR and audio performance. The three-level, Σ - Δ Class-D modulator is designed to provide the least amount of EMI, the lowest quiescent power dissipation, and the highest audio efficiency without sacrificing audio quality.

The audio input is provided via a serial audio interface that can be programmed to accept all common audio formats, including I²S, TDM, and PDM. Control of the IC is provided via an I²C control interface. An alternative to I²C control is standalone operation mode, which allows several settings that are adjusted by off-chip external resistors. The **SSM2529** can accept a variety of input MCLK frequencies and can use BCLK as the clock source in some configurations. An integrated PLL can also provide the device master clock.

The integrated DSP includes soft digital volume control circuits; a de-emphasis, high-pass filter; a seven-band programmable equalizer; and a programmable digital dynamic range compressor. In addition, the part includes a feedforward speaker temperature prediction module to protect the loudspeaker.

The **SSM2529** supports single-supply mode, where DVDD is provided by the on-chip LDO regulator, eliminating the need for an external digital core supply.

The digital interface is very flexible and convenient. It can offer a better system solution for other products whose sole audio source is digital, such as wireless speakers, laptop PCs, portable digital televisions, and navigation systems.

The **SSM2529** is specified over the industrial temperature range of -40°C to +85°C. It has built-in thermal shutdown and output short-circuit protection. It is available in a 16-ball, 1.92 mm \times 1.94 mm wafer level chip scale package (WLCSP).

ABSOLUTE MAXIMUM RATINGS

Absolute maximum ratings apply at 25°C, unless otherwise noted.

Table 6.

Parameter	Rating
SPKVDD Supply Voltage	−0.3 V to +5.5 V
DVDD Supply Voltage	−0.3 V to +1.98 V
Input Voltage (Signal Source)	−0.3 V to +3.6 V
ESD Susceptibility	4 kV
Storage Temperature Range	−65°C to +150°C
Operating Temperature Range	−40°C to +85°C
Junction Temperature Range	−65°C to +165°C
Lead Temperature (Soldering, 60 sec)	300°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

THERMAL RESISTANCE

θ_{JA} is specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.

Table 7. Thermal Resistance

Package Type	θ_{JA}	Unit
16-Ball, 1.92 mm × 1.94 mm WLCSP	56.1	°C/W

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

THEORY OF OPERATION

OVERVIEW

The [SSM2529](#) is a fully integrated, mono, digital switching audio amplifier. The [SSM2529](#) receives digital audio inputs and produces the PDM differential switching outputs using the internal power stage. The part has built-in protections for overtemperature and overcurrent conditions. The [SSM2529](#) also has built-in soft turn-on and soft turn-off for pop-and-click suppression. The part has programmable register control via the I²C port.

MASTER CLOCK

In master mode, the built-in PLL can provide the master clock. In slave mode, the [SSM2529](#) receives an external clock at the MCLK or BCLK input pin. The external clock must be fully synchronous with the incoming digital audio on the serial interface. The internal clock for the [SSM2529](#) always runs at 5.6448 MHz to 8.192 MHz, depending on the input sample rate. The three options for providing the master clock to the part are as follows:

- Using the clock generated by the built-in PLL
- Using the BCLK pin
- Using the MCLK pin

The MCLK option can use the built-in PLL or the BCLK pin to generate the internal clock as long as the clock is provided at the same rate that is required by the MCLK pin. By setting the PLEN bit in Register 0x0E, this is enabled. In this case, there is no need to provide the master clock to the MCLK pin, which in turn saves a pin connection from the audio source. If using the MCLK pin, various multiples of the sample frequency can be used for MCLK. See Table 48 for all available options and settings. When the [SSM2529](#) enters its power-down state, it is possible to gate this clock to further conserve system power. However, an MCLK must be present for the audio amplifier to operate. The input MCLK rate is determined by setting the MCS bits in Register 0x00. For more information, see Table 48.

INTERNAL CLOCK GENERATOR

The digital core clock can be derived directly from the external clock, or it can be generated using the PLL. Clocks for the DSPs, the serial ports, and the converters are derived from the core clock. The core clock rate is always an integer multiple of the sample rate used for the part.

The clock generation block is composed of a digital PLL and an analog PLL. The analog PLL can accept input frequencies in the 8 MHz to 27 MHz range. To support lower frequencies (8 kHz to 8 MHz), the chip provides a digital PLL. It can boost the input clock frequency by 2^N , where $N = 1$ to 10.

Figure 25 shows the clock generation block diagram.

For the digital PLL, the source clock is selected by the DPLL_REF_SEL bits (Register 0x08), and the frequency relationship between the DPLL input and the output clock is defined by the DPLL_NDIV bit.

The frequency relationship between the APLL input and output is

$$f_{PLL} = f_{IN} \times (R + (N/M)) / X$$

where R , N , M , and X are defined by the corresponding PLL registers (Register 0x09 to Register 0x0D).

DIGITAL INPUT SERIAL AUDIO INTERFACE

The [SSM2529](#) includes a standard serial audio interface that is slave only. The interface is capable of receiving I²S, left justified, right justified, PCM/TDM, or PDM input formats. The number of data bits must be set when in right-justified mode only.

Figure 25. Clock Generation Block Diagram

PDM MODE SETUP AND CONTROL

If the ADDR pin is tied to DVDD while in standalone mode, or the PDM_MODE bit (Register 0x01, Bit 7) is set to 1 while in I²C mode, the SSM2529 operates in PDM mode. In PDM mode, the SDATA pin receives the 1-bit PDM input to the DAC, and the BCLK pin provides the system clock for registering the input data. The PDM data input is registered directly on each clock edge.

The left or right data can be registered on either the rising or falling BCLK edge in both standalone mode or in I²C mode by setting the BCLK_EDGE bit (Register 0x03, Bit 0).

When the part is in standalone mode and the PDM interface is selected, pull the MCLK pin to logic level low to register the left channel data (L data) on the rising BCLK edge, and the right channel data (R data) on the falling BCLK edge. When the MCLK pin is connected to logic high, the R data is registered on the rising BCLK edge, and the L data is registered on the falling BCLK edge.

When this part is in I²C PDM mode, if BCLK_EDGE = 0, the L data is registered on the rising BCLK edge and the R data is registered on the falling BCLK edge. If BCLK_EDGE = 1, the L data is registered on the falling BCLK edge, and the R data is registered on the rising BCLK edge.

Figure 26. PDM Input Format

HIGH-PASS FILTER

The audio processing block contains a configurable first-order, high-pass filter. When the high-pass filter is enabled, the dc values are continuously calculated and subtracted from the input signal. By setting HPFOR (Register 0x15, Bit 1), the last calculated dc value is stored. When the high-pass filter is disabled, the stored value is still subtracted from the input signal until the HPFOR is cleared to 0.

The high-pass filter can work in audio mode or application mode, as configured by the HPF_CTRL register. In audio mode, the high-pass filter's 3 dB cutoff frequency is 3.7 Hz when the

sampling rate is 48 kHz. In application mode, the 3 dB cutoff frequency varies from 50 Hz to 750 Hz, which is selected by using the HPFCUT bits (Register 0x15, Bits[5:2]).

FULLY PROGRAMMABLE SEVEN-BAND EQUALIZER

The programmable seven-band equalizer comprises five biquad filters (Band 1 to Band 5) and two first-order IIR filters (Band 6 and Band 7). Figure 28 shows the system block diagram.

All filter coefficients are programmable via the corresponding registers. When not all five midfrequency bands are needed, the filter bank can be configured as other filters, such as de-emphasis and notch filters.

To operate as a seven-band equalizer, the two first-order IIR filters are usually configured as one low-pass shelving filter and one high-pass shelving filter, and the biquad filters are configured as peak filters. By using the coefficient registers, the cutoff frequencies and peak gains of the shelving filters and the center frequencies and bandwidths of the peak filters are programmable. For frequency bands lower than 200 Hz, the low-pass shelving filter is suggested.

Figure 28. System Block Diagram

The common biquad filter transfer function is

$$H(z) = \frac{P0 + P1 \times Z^{-1} + P2 \times Z^{-2}}{1 - D1 \times Z^{-1} - D2 \times Z^{-2}}$$

The first-order IIR filter transfer function is

$$H(z) = \frac{P0 + P1 \times Z^{-1}}{1 - D1 \times Z^{-1}}$$

In normal mode, the supported coefficients range from -4 to approximately $+4$. For equalizer mode, this range means that the cutoff and center frequencies can vary from 40 Hz to 12 kHz when the input sampling rate is 48 kHz, and the peak gain varies from -18 dB to $+18$ dB.

The EQ_FORMAT bit in Register 0x54 defines the coefficient format. The default value is 0, and the corresponding format is Q3.13. Setting this bit to 1 achieves a larger coefficient range (from -8 to approximately $+8$), which enables a larger gain boost or decreases the range.

Online coefficient update is supported. If the filter bank coefficients are updated when the EQ is operating, set the EQ_UPD bit after the coefficient is written. The coefficient update procedure requires approximately 0.05 ms to complete. The read only bit, EQ_UPDING, in the EQ_CTRL1 register represents the coefficient update status. If the system clock is removed during this period, the update procedure cannot be finished, and the EQ_UPD_CLR bit must be set to cancel this update.

The filter bank can be disabled, and all seven bands can be bypassed separately to save power. The corresponding bits are EQEN and EQBP1 to EQBP7 in Register 0x55.

DYNAMIC RANGE CONTROL

The dynamic range control function is used to alter (usually reduce) the dynamic range of the audio signal so that a loud signal can be heard without disturbing the hearing perception, and a weak signal can still be heard. In addition, very large signals and very weak signals are usually treated with different methods to ensure the overall sound quality. The DRC functions include the following:

- Limiter
- Compressor
- Expander
- Noise Gate

The dynamic range is not altered when the signal level is in the middle. These functions can be enabled or disabled individually.

Limiter

If the input audio samples are large, the output is clipped at a predefined level so that the speakers are not overdriven.

If the ADC power tracking function is enabled, the maximum output level is set automatically to correspond to the speaker SPKVDD power.

Compressor

The compressor is used to reduce the signal dynamic range when the input level is large and within predefined boundaries. This helps reduce the loudness when the signal level is high.

Expander

The expander is used to increase the signal dynamic range when the input signal level is small and within predefined upper and lower boundaries. This helps increase the loudness when the signal is weak.

Noise Gate

When the signal level is lower than a predefined threshold level, it is treated as noise. Under this condition, the output is set to zero.

The overall DRC characteristics are illustrated in Figure 37. A number of threshold levels (referred to the input) are used, which are defined as the limiter threshold (LT), compressor threshold (CT), expander threshold (ET), noise gate threshold (NT), maximum output signal amplitude (SMAX), and minimum output signal amplitude (SMIN). The corresponding bits are DRC_LT, DRC_CT, DRC_ET, DRC_NT, DRC_SMAX, and DRC_SMIN and can be found in Register 0x59 to Register 0x5D.

Figure 37. DRC Input/Output Relationship

DRC MODE CONTROL

The DRC_EN bits in Register 0x60 control the DRC. The noise gating function can be disabled by setting the NG_EN bit in Register 0x60.

Figure 38. DRC Block Diagram

Level Measurement

The DRC level measurement includes the peak and rms value measurements. The parameters that affect the peak measurement are attack time and release time (AT and RT). The parameter that affects the rms measurement is average time (T_{AV}). The attack time can vary from 0 ms to 1.536 sec; the release time and average time can vary from 0 ms to 24.576 sec. The corresponding bits are PEAK_ATT, PEAK_REL, and DRCLTAV and can be found in Register 0x56 and Register 0x57.

Static Curve

The static curve is the DRC core function used to define the targeted input and output relationship. The role for the DRC block is to find the appropriate gain values with the various signal levels. To change the dynamic range of the original audio signal, the gain values vary with the input signal level.

An example of such a static curve is given in Figure 39, which shows the input and output signal levels. The blue line shows a linear relationship where the output dynamic range is identical to the input dynamic range. The red line shows a different output dynamic range from the input. Furthermore, this curve indicates that the signal dynamic range is larger when the input signal is low.

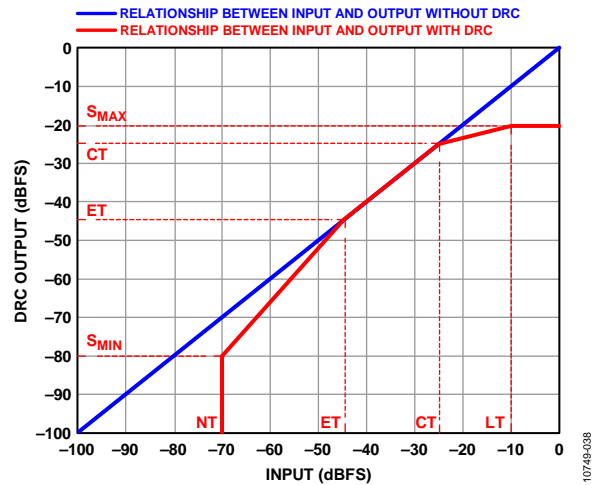

Figure 39. DRC Output vs. Input

Figure 40 shows the gain values at various input signal levels.

Figure 40. DRC Gain vs. Input

DRC Static Curve Function

A number of threshold levels (referred to the input) are used in Figure 39 and Figure 40; these levels are defined as the limiter threshold (LT), compressor threshold (CT), expander threshold (ET), noise gate threshold (NT), maximum output signal amplitude (SMAX), and minimum output signal amplitude (SMIN). The corresponding bits, DRC_LT, DRC_CT, DRC_ET, DRC_NT, DRC_SMAX, DRC_SMIN, can be found in Register 0x59 to Register 0x5D.

DRC Gain Smooth

Before the gain calculated by the static curve function multiplies with the input signal, smooth it to ensure that it does not change rapidly for this can lead to noise.

The gain smooth is affected by its attack and decay time parameters. The attack time can vary from 0 ms to 1.536 sec, while the decay time can vary from 0 ms to 24.576 sec. The corresponding bits are DRC_ATT and DRC_DEC and can be found in Register 0x58.

DRC Hold Time

Two types of hold time are used in the DRC. One is used in normal mode to prevent the calculated gain from increasing too quickly, and the other is used during DRC transiting from expander mode to noise gating mode to prevent the DRC from entering noise gating too quickly. The DRCHTNOR and DRCHTNG bits in Register 0x5E set which type is used.

GAIN RIPPLE REMOVE

Due to the swing of the peak/rms value detected by the level measurement, the gain to apply to the input signal has a little ripple, which leads to the modulation of the output signal. The ripple remove function suppresses this effect. The ripple threshold is defined by the DRCRRH bit in Register 0x5F.

SPEAKER PROTECTION

The IC includes a speaker temperature prediction module to protect the loudspeaker. Loudspeakers can be damaged when the voice coil overheats due to operation higher than the rated power. Typically, the thermal time constants of the loudspeakers are long, approximately 1 sec for voice coil and 60 sec for core. They can handle momentary power spikes without overheating; however, they cannot handle sustained high power. The speaker protection method used in the IC can reduce the volume when the temperature of the loudspeaker exceeds the temperature threshold set by the user while preserving the maximum power

of the loudspeaker. The temperature prediction method is based on the general thermal model of the loudspeaker.

In this thermal model, R1, R2, C1, and C2 are temperature coefficients derived by measuring loudspeaker characteristics. They are set by the I²C control registers, Register 0x84 to Register 0x8B (SP_CF1_H, SP_CF1_L, SP_CF2_H, SP_CF2_L, SP_CF3_H, SP_CF3_L, SP_CF4_H and SP_CF4_L).

Other critical parameters needed include ambient temperature, dc resistance of the loudspeaker, and temperature coefficient of the voice coil material. These parameters are set by Register 0x81 to Register 0x83 (TEMP_AMBIENT, SPKR_DCR, and SPKR_TC).

After running the thermal model by setting the speaker protection enable bit (SP_EN, Register 0x80), the speaker voice coil temperature status and speaker magnet temperature status can be obtained by an I²C reading of the SPKR_TEMP register (Register 0x8C) and the SPKR_TEMP_MAG register (Register 0x8D). The user sets the voice coil temperature threshold (maximum speaker voice coil temperature before gain reduction occurs) by using the MAX_SPKR_TEMP register (Register 0x8E). If this threshold is crossed, the output volume is reduced according to the speed set by the SP_AR bits (speaker protection gain reduction attack rate, Register 0x8F, Bits[7:4]) and the SP_RR bits (speaker protection gain reduction release rate, Register 0x8F, Bits[3:0]).

POWER SUPPLIES

The SSM2529 has two internal power supplies that must be provided: SPKVDD and DVDD. The SPKVDD supply powers to the full bridge power stage of the MOSFET and its associated drive, control, and protection circuitry. SPKVDD can operate from 2.5 V to 5.5 V and must be present to obtain audio output. Lowering the SPKVDD supply results in lower output power and correspondingly lower power consumption, and it does not affect audio performance.

DVDD provides power to the digital logic and analog components. DVDD can operate from 1.08 V to 1.98 V, and it must be provided to write to the I²C or to obtain audio output. Lowering the supply voltage results in lower power consumption; however, it also results in lower audio performance.

POWER CONTROL

The SSM2529 includes various programmable power-down modes that are contained in the first I²C register (Register 0x00), power/reset control. By default, the IC is set in software power-down, which is the I²C programmable master power-down. Only I²C functionality operates when in software power-down mode.

The SSM2529 also contains a smart power-down feature that, when enabled, looks at the incoming digital audio. In addition, if the audio is zero for 1024 consecutive samples, regardless of sample rate, it puts the IC in a smart power-down state. In this state, all circuitry, except the I²S and I²C ports, are placed in a low power state. After a single nonzero input is received, the SSM2529 leaves this state and resumes normal operation.

POWER-ON RESET/VOLTAGE SUPERVISOR

The [SSM2529](#) includes an internal power-on reset and voltage supervisor circuit. This circuit provides an internal reset to all circuitry during initial power-up. It also monitors the power supplies to the IC, and it mutes the outputs and issues a reset when the voltages are lower than the minimum operating range. This ensures that no damage due to low voltage operation occurs and that no pops can occur under nearly any power removal conditions.

STANDALONE MODE

When the SA_MODE pin is pulled high, the [SSM2529](#) can operate without any I²C control. In this mode, the automatic sample rate detection and smart power-down are always enabled. Volume Control A and Volume Control B can be controlled via the SCL and SDA pins.

In standalone mode, the DRC function is disabled. The EQ and HPF are also disabled. When ADDR = 1, the input interface is PDM. Otherwise, I²S and TDM serial interface formats can be selected via MCLK. In standalone mode, the working clock is generated by the internal PLL.

Table 39. Standalone Mode Pin Configuration

Conventional Operation Pin	SA_MODE = 1
SCL	Volume Control A
SDA	Volume Control B

MCLK	0: I ² S (ADDR = 0) or PDM L channel (ADDR = 1) 1: TDM (ADDR = 0) or PDM R channel (ADDR = 1)

I²C PORT

The [SSM2529](#) supports a 2-wire serial (I²C-compatible) micro-processor bus driving multiple peripherals. Two pins, serial data (SDA) and serial clock (SCL), carry information between the [SSM2529](#) and the system I²C master controller. The [SSM2529](#) is always a slave on the bus, meaning that it cannot initiate a data transfer. Each slave device is recognized by a unique address. The address byte format is shown in Table 40. The address resides in the first seven bits of the I²C write. The LSB of this byte either sets a read or write operation. Logic Level 1 corresponds to a read operation, and Logic Level 0 corresponds to a write operation. The full byte addresses are shown in Figure 41, where the subaddresses are automatically incremented at word boundaries, and can be used for writing large amounts of data to contiguous memory locations. This increment happens automatically after a single-word write unless a stop condition is encountered. A data transfer is always terminated by a stop condition.

Both SDA and SCL must have a 2.2 k Ω pull-up resistor on the lines connected to them. The voltage on these signal lines must not be more than 3.6 V.

Table 40. I²C Address Byte Format

Bit 0	Bit 1	Bit 2	Bit 3	Bit 4	Bit 5	Bit 6	Bit 7
0	1	1	0	1	0	0	R/W

Addressing

Initially, each device on the I²C bus is in an idle state, monitoring the SDA and SCL lines for a start condition and the proper address. The I²C master initiates a data transfer by establishing a start condition, defined by a high-to-low transition on SDA, while SCL remains high. This indicates that an address/data stream follows. All devices on the bus respond to the start condition and shift the next eight bits (the 7-bit address plus the R/W bit) MSB first. The device that recognizes the transmitted address responds by pulling the data line low during the ninth clock pulse. The device address for the [SSM2529](#) is 0x34. The ninth bit is known as the acknowledge bit. All other devices withdraw from the bus at this point and return to the idle condition.

The R/W bit determines the direction of the data. A Logic 0 on the LSB of the first byte means that the master writes information to the peripheral, whereas a Logic 1 means that the master reads information from the peripheral after writing the subaddress and repeating the start address. A data transfer takes place until a stop condition is encountered. A stop condition occurs when SDA transitions from low to high while SCL is held high. The timing for the I²C port is shown in Figure 3.

Stop and start conditions can be detected at any stage during the data transfer. If these conditions are asserted out of sequence with normal read and write operations, the [SSM2529](#) immediately jumps to the idle condition. During an SCL high period, issue only one start condition, one stop condition, or a single stop condition followed by a single start condition. If an invalid subaddress is issued, the [SSM2529](#) does not issue an acknowledge and returns to the idle condition. If the highest subaddress is exceeded while in auto-increment mode, one of two actions is taken. In read mode, the [SSM2529](#) outputs the highest subaddress register contents until the master device issues a no acknowledge, indicating the end of the read. When the SDA line is not pulled low on the ninth clock pulse of SCL, a no acknowledge occurs. If the highest subaddress location is reached while in write mode, the data for the invalid byte is not loaded into any subaddress register, a no acknowledge is issued by the [SSM2529](#), and the part returns to the idle condition.

I²C Read and Write Operations

Table 42 shows the timing of a single-word write operation. Every ninth clock, the SSM2529 issues an acknowledge by pulling SDA low.

Table 43 shows the timing of a burst mode write sequence as an example where the target destination registers are two bytes. The SSM2529 knows to increment its subaddress register every byte because the requested subaddress corresponds to a register or memory area with a byte word length.

The timing of a single-word read operation is shown in Table 44. Note that the first R/W bit is 0, indicating a write operation. This is because the subaddress still needs to be written to set up the internal address. After the SSM2529 acknowledges the receipt of the subaddress, the master must issue a repeated start command

followed by the chip address byte with the R/W bit set to 1 (read). This causes the SSM2529 SDA to reverse and begin driving data back to the master. The master then responds every ninth pulse with an acknowledge pulse to the SSM2529.

Table 42 to Table 45 use the abbreviations shown in Table 41.

REGISTER SUMMARY

The SSM2529 contains eighteen 8-bit registers that can be accessed via the I²C port. See Table 46 for the control register mapping. The register settings are described in detail in Table 47 through Table 159.

Table 46.

Hex	Name	Bits	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Reset	RW

REGISTER DETAILS

SOFTWARE RESET AND MASTER SOFTWARE POWER-DOWN CONTROL (PWR_CTRL) REGISTER

Table 47. Address: 0x00, Reset: 0x23, Name: PWR_CTRL

Bits	Bit Name	Settings	Description	Reset	Access
7	SYS_RST	0 1	Software reset Normal operation Software reset	0x0	RW
6	APWDN_ANA	0 1	Auto power-down mode Only digital Both analog and digital	0x0	RW
5	APWDN_EN	0 1	Auto power-down enable Auto power-down disabled Auto power-down enabled	0x1	RW
4	LP_MODE	0 1	Low power mode Normal operation Low power operation mode; DAC runs at half speed	0x0	RW
[3:1]	MCS	000 001 010 011 100 101 110 111	Master clock rate selection Refer to Table 48 Refer to Table 48 Refer to Table 48 Refer to Table 48 Refer to Table 48 Refer to Table 48 Not applicable Not applicable	0x1	RW
0	SPWDN	0 1	Master software power-down Normal operation Software master power-down	0x1	RW

Table 48 shows the MCS bit settings available with the possible input sample rates vs. the required master clock frequency, as well as the master clock to bit clock ratio. The b110 thru b111 settings are reserved and not available to the user.

MCLK RATIO AND FREQUENCY

Table 48. MCS Bit Field Setting—MCLK Ratio and Frequency (N/A = Not Applicable)

Input Sample Frequency, f_s (kHz)		Setting 0 b000	Setting 1 b001	Setting 2 b010	Setting 3 b011	Setting 4 b100	Setting 5 b101	Setting 6 b110 thru b111
8	Ratio MCLK	768 f_s 6.144 MHz	1024 f_s 8.192 MHz	1536 f_s 12.288 MHz	2048 f_s 16.384 MHz	3072 f_s 24.576 MHz	4096 f_s 32.768 MHz	Reserved
11.025	Ratio MCLK	N/A	512 f_s 5.6448 MHz	1024 f_s 11.2896 MHz	1536 f_s 16.9344 MHz	2048 f_s 22.5792 MHz	3072 f_s 33.8688 MHz	Reserved
12	Ratio MCLK	N/A	512 f_s 6.144 MHz	1024 f_s 12.288 MHz	1536 f_s 18.432 MHz	2048 f_s 24.576 MHz	3072 f_s 38.864 MHz	Reserved
16	Ratio MCLK	384 f_s 6.144 MHz	512 f_s 8.192 MHz	768 f_s 12.288 MHz	1024 f_s 16.384 MHz	1536 f_s 24.576 MHz	2048 f_s 32.768 MHz	Reserved
22.05	Ratio MCLK	N/A	256 f_s 5.6448 MHz	512 f_s 11.2896 MHz	768 f_s 16.9344 MHz	1024 f_s 22.5792 MHz	1536 f_s 33.8688 MHz	Reserved
24	Ratio MCLK	N/A	256 f_s 6.144 MHz	512 f_s 12.288 MHz	768 f_s 18.432 MHz	1024 f_s 24.576 MHz	1536 f_s 38.864 MHz	Reserved
32	Ratio MCLK	192 f_s 6.144 MHz	256 f_s 8.192 MHz	384 f_s 12.288 MHz	512 f_s 16.384 MHz	768 f_s 24.576 MHz	1024 f_s 32.768 MHz	Reserved
44.1	Ratio MCLK	N/A	128 f_s 5.6448 MHz	256 f_s 11.2896 MHz	384 f_s 16.9344 MHz	512 f_s 22.5792 MHz	768 f_s 33.8688 MHz	Reserved

Input Sample Frequency, f_s (kHz)		Setting 0 b000	Setting 1 b001	Setting 2 b010	Setting 3 b011	Setting 4 b100	Setting 5 b101	Setting 6 b110 thru b111
48	Ratio MCLK	N/A	128 f_s 6.144 MHz	256 f_s 12.288 MHz	384 f_s 18.432 MHz	512 f_s 24.576 MHz	768 f_s 36.864 MHz	Reserved
88.2	Ratio MCLK	N/A	64 f_s 5.6448 MHz	128 f_s 11.2896 MHz	192 f_s 16.9344 MHz	256 f_s 22.5792 MHz	384 f_s 33.8688 MHz	Reserved
96	Ratio MCLK	N/A	64 f_s 6.144 MHz	128 f_s 12.288 MHz	192 f_s 18.432 MHz	256 f_s 24.576 MHz	384 f_s 36.864 MHz	Reserved

When using MCS = 0/64 f_s mode, the chip automatically operates in low power mode.

EDGE SPEED AND CLOCKING CONTROL (SYS_CTRL) REGISTER

Table 49. Address: 0x01, Reset: 0x20, Name: SYS_CTRL

Bits	Bit Name	Settings	Description	Reset	Access
7	PDM_MODE	0 1	PDM input enable Disable PDM input Enable PDM input	0x0	RW
6	PDM_FS	0 1	PDM input sample rate About 3 MHz sample rate About 6 MHz sample rate	0x0	RW
5	PDB_ADC	0 1	ADC power down Power down Power on	0x1	RW
4	BCLK_RATE	0 1	BCLK cycles per channel frame 32 cycles per channel 16 cycles per channel	0x0	RW
3	BCLK_GEN	0 1	Generate BCLK internally Disabled Enabled	0x0	RW
[2:1]	EDGE	00 01	Edge rate control Normal operation Low EMI mode operation	0x0	RW
0	ASR	0 1	Auto sample rate Sample rate setting determined by MCS register (Register 0x00, Bits[3:1]) Automatic sample rate detection	0x0	RW

SERIAL AUDIO INTERFACE AND SAMPLE RATE CONTROL (SAI_FMT1) REGISTER

Table 50. Address: 0x02, Reset: 0x02, Name: SAI_FMT1

Bits	Bit Name	Settings	Description	Reset	Access
[7:6]	SDATA_FMT	00 01 10 11	Serial data format I ² S, BCLK delay by 1 Left justified Right justified, 24-bit data Right justified, 16-bit data	0x0	RW
[5:3]	SAI	000 001 010 011 100 101 110 111	Serial audio interface format Stereo I ² S, left justified, right justified TDM2 TDM4 TDM8 TDM16 Mono PCM Reserved Reserved	0x0	RW

Bits	Bit Name	Settings	Description	Reset	Access
[2:0]	SR	000 001 010 011 100 101 110 111	Sample rate selection 11.025 kHz, 12 kHz 22.05 kHz, 24 kHz 44.1 kHz, 48 kHz 96 kHz 8 kHz 16 kHz 32 kHz Reserved	0x2	RW

SERIAL AUDIO INTERFACE CONTROL (SAI_FMT2) REGISTER

Table 51. Address: 0x03, Reset: 0x00, Name: SAI_FMT2

Bits	Bit Name	Settings	Description	Reset	Access
7	LPST	0 1	Small power stage enable Disabled Enabled	0x0	RW
[6:5]	LR_SEL	00 01 10 11	L/R channel selector Select left channel Select right channel Select (left + right)/2 Select (left – right)/2	0x0	RW
4	LRCLK_MODE	0 1	LRCLK mode selection for TDM operation 50% duty cycle LRCLK Pulse mode LRCLK	0x0	RW
3	LRCLK_POL	0 1	LRCLK polarity control Normal LRCLK operation Inverted LRCLK operation	0x0	RW
2	SAI_MSB	0 1	SDATA bit stream order MSB first SDATA LSB first SDATA	0x0	RW
1	BCLK_TDMC	0 1	BCLK cycles per frame in TDM modes select 32 BCLK cycles per slot 16 BCLK cycles per slot	0x0	RW
0	BCLK_EDGE	0 1	BCLK active edge select Rising BCLK edge used (if PDM_MODE = 1, L data is registered on the rising edge, and R data is registered on the falling edge) Falling BCLK edge used (if PDM_MODE = 1, R data is registered on the rising edge, and L data is registered on the falling edge)	0x0	RW

CHANNEL MAPPING CONTROL REGISTER

Table 52. Address: 0x04, Reset: 0x10, Name: Channel Mapping Control

Bits	Bit Name	Settings	Description	Reset	Access
[7:4]	CH_SEL_R	0000 0001 0010 0011 0100 0101 0110 0111 1000 1001 1010 1011 1100 1101 1110 1111	Right channel mapping select Channel 0 from SAI to right output Channel 1 from SAI to right output Channel 2 from SAI to right output Channel 3 from SAI to right output Channel 4 from SAI to right output Channel 5 from SAI to right output Channel 6 from SAI to right output Channel 7 from SAI to right output Channel 8 from SAI to right output Channel 9 from SAI to right output Channel 10 from SAI to right output Channel 11 from SAI to right output Channel 12 from SAI to right output Channel 13 from SAI to right output Channel 14 from SAI to right output Channel 15 from SAI to right output	0x1	RW
